☆ THE ART OF COMPUTER PROGRAMMING ☆

☆☆☆☆ ERRATA TO VOLUME 1 (3rd edition) ☆☆☆☆

This document is a transcript of the notes that I have been making in my personal copy of *The Art of Computer Programming*, Volume 1 (third edition) since it was first printed in 1997.

Four levels of updates — "errors," "amendments," "plans," and "improvements" — appear, indicated by four different typographic conventions:

▸**Page 666** line 1 ——— 04 Jul 1776

Technical or typographical errors (aka bugs) are the most critical items, so they are flagged with a '▸' preceding the page number. The date on which I first was told about the bug is shown; this is the effective date on which I paid the finder's fee. The necessary corrections are indicated in a straightforward way. If, for example, the book says 'n' where it should have said '$n+1$', the change is shown thus:

$n \mathrel{\not\rightarrow} n+1$

Page 666 line 2 ——— 14 Jul 1789

Amendments to the text appear in the same format as bugs, but without the '▸'. These are things I wish I had known about or thought of when I wrote the original text, so I added them later. The date is the date I drafted the new text.

Page 666 line 3 . . . . . 20 Nov 1917

Plans for the future represent a third kind of item. In such notes I sketched my intentions about things that I wasn't ready to flesh out further when I wrote them down. You can identify these items because they're written in slanted type, and preceded by a bunch of dots '. . . . . ' leading to the date on which I recorded the plan in my files.

Page 666 line 4 ——— 10 Jan 1938

The fourth and final category — indicated by page and line number in smaller, slanted type — consists of minor corrections or improvements that most readers don't want to know about, because they are so trivial. You wouldn't even be seeing these items if you hadn't specifically chosen to print the complete errata list in all its gory details. Are you sure you wanted to do that?

My shelves at home are bursting with preprints and reprints of significant research results that I want to digest and summarize, where appropriate, in the ultimate edition of Volume 1. I didn't do that in the third edition because I would surely have to do it over again later: New results continue to pour forth at a great rate, and I will have time to rewrite that volume only once. Volumes 4 and 5 need to be finished first. So I've put most of my effort so far into writing up those parts of the total picture that seem to have converged to their near-final form. It follows, somewhat paradoxically, that the updates in this document are most current in the areas where there has been least activity.

On the other hand I do believe that the changes listed here bring Volume 1 completely up to date in two respects: (1) All of the research problems in the previous edition — i.e., all exercises that were rated 46 and above — have received new ratings of 45 or less whenever I learned of a solution; and in such cases, the answer now refers to that solution. (2) All of the historical information about pioneering developments has been amended whenever new details have come to my attention.

The ultimate, glorious, future editions of Volumes 1–3 are works in progress. Please let me know of any improvements that you think I ought to make. Send your comments either by snail mail to D. E. Knuth, Computer Science, Gates Building 4B, Stanford University, Stanford CA 94305-9045, or by email to `taocp@cs.stanford.edu`. *(Use email for book suggestions only, please — all other correspondence is returned unread to the sender, or discarded, because I have no time to read ordinary email.) Although I'm working full time on Volume 4B these days, I will try to reply to all such messages within a year of receipt. Current news about The Art of Computer Programming is posted on*

`http://www-cs-faculty.stanford.edu/~knuth/taocp.html`

and updated regularly.

—Don Knuth, April 1997

What happened?
The subject took the bit in its teeth and ran away with it,
that's what happened.
I know now how Sir James Frazer felt when,
after setting out to dash off a brief monograph
on a single obscure rite, he found himself
in the embarrassing possession of
the 12 volumes of "The Golden Bough."

— WAVERLEY ROOT (1974)

$(V_0, V_1, \ldots, V_n)$ is a *path* ... vertex to itself. ↝ $(V_0, V_1, \ldots, V_n)$ is a *walk* of length n from V to V' if $V = V_0$, V_k is adjacent to V_{k+1} for $0 \le k < n$, and $V_n = V'$. The walk is a *path* if vertices V_0, V_1, ..., V_n are distinct; it is a *cycle* if V_0 through V_{n-1} are distinct, $V_n = V_0$, and $n \ge 3$. Sometimes we are less precise, and refer to a cycle as "a path from a vertex to itself." We often speak of a "simple path" to emphasize the fact that we're talking about a path instead of an arbitrary walk. A graph is *connected* if there is a path between any two vertices of the graph.

56. 210 310 320 321 410 420 421 430 431 432 510 520 521 530 531 532 540 541 542 543 610. With a fixed, b and c run through the combinations of a things two at a time; with a and b fixed, c runs through the combinations of b things one at a time.

Similarly, we could express all numbers in the form $n = \binom{a}{4} + \binom{b}{3} + \binom{c}{2} + \binom{d}{1}$ with $a > b > c > d \geq 0$; the sequence begins 3210 4210 4310 4320 4321 5210 5310 5320 .... We can find the combinatorial representation by a "greedy" method, first choosing the largest possible a, then the largest possible b for $n - \binom{a}{4}$, etc. [Section 7.2.1.3 discusses further properties of this representation.]

Page 489 replacement for first three lines of answer 58 — 12 Jun 2003

58. [*Systematisches Lehrbuch der Arithmetik* (Leipzig: 1811), xxix.] Use induction and

$$\binom{n}{k}_q = \binom{n-1}{k}_q + \binom{n-1}{k-1}_q q^{n-k} = \binom{n-1}{k}_q q^k + \binom{n-1}{k-1}_q.$$

Therefore [F. Schweins, *Analysis* (Heidelberg: 1820), §151] the q-generalization of (21) is

Page 490 replacement for lines 5–7 — 12 Jun 2003

For further information, see G. Gasper and M. Rahman, *Basic Hypergeometric Series* (Cambridge Univ. Press, 1990). Page 491 replacement for answer 66 — 08 Nov 2005

66. Let $X = \binom{x}{n}$, $\underline{X} = \binom{x}{n-1} = \frac{n}{x-n+1}X$, $\overline{X} = \binom{x}{n+1} = \frac{x-n}{n+1}X$, with similar notations for Y and Z. We may assume that $y > n-1$ is fixed, so that x is a function of z.

Let $F(z) = \overline{X} - \overline{Y} - \overline{Z}$, and suppose that $F(z) = 0$ for some $z > n-2$. We will prove that $F'(z) < 0$; therefore $z = y$ must be the only root $> n-2$, proving the second inequality. Since $F(z) = \frac{x-n}{n+1}(Y+Z) - \frac{y-n}{n+1}Y - \frac{z-n+1}{n}Z = 0$ and $x > y$ and $Y, Z > 0$, we must have $\frac{x-n}{n+1} < \frac{z-n+1}{n}$. Setting $X' = dX/dx$ and $Z' = dZ/dz = dX/dz$, we have

$$\frac{X'}{X} = \frac{1}{x} + \frac{1}{x-1} + \cdots + \frac{1}{x-n+1} > \frac{n}{n+1}\left(\frac{1}{z} + \cdots + \frac{1}{z-n+2}\right) = \frac{n}{n+1}\frac{Z'}{Z},$$

since $\frac{x-n+1}{n+1} < \frac{z-n+2}{n}, \ldots, \frac{x-1}{n+1} < \frac{z}{n}$. Thus $dx/dz = Z'/X' < \frac{n+1}{n}(Z/X)$, and

$$F'(z) = \frac{X}{n+1}\frac{dx}{dz} + \frac{x-n}{n+1}Z' - \frac{Z}{n} - \frac{z-n+1}{n}Z' < \left(\frac{x-n}{n+1} - \frac{z-n+1}{n}\right)Z' < 0.$$

To prove the first inequality, we may assume that $n > 2$. Then if $\underline{X} = \underline{Y} + \underline{Z}$ for some $z > n-2$, the second inequality tells us that $z = y$.

12. M. Hofri and P. Jacquet [*Algorithmica* **22** (1998), 516–528] have analyzed the case when the $m \times n$ matrix entries are distinct and in random order. The running times of the two `MIX` programs are then respectively $\bigl(6mn+5mH_n+8m+6+5(m+1)/(n-1)\bigr)u+O\bigl((m+n)^2/\binom{m+n}{m}\bigr)$ and $(5mn+2nH_m+7m+7n+9H_n)u+O(1/n)+O\bigl((\log n)^2/m\bigr)$, as $m \to \infty$ and $n \to \infty$, assuming that $(\log n)/m \to 0$.

Page 516 answer 14 ——— 31 Aug 1998

[Udo Wermuth has indeed squeezed out an additional $9u$, $10u$, or $12u$, depending on the year. But details are omitted here because `MIX` will soon be replaced.]

▸**Page 542** new answer for exercise 11 — 04 Oct 2005

11. Counting as before, we find that the expected number is

$$E_{mnt} = \frac{1}{n^m}\binom{n}{2}\sum_{k=1}^{m}\sum_{r\ge t}(k-1)\binom{k-2}{r}(n-1)^{k-2-r}n^{m-k};$$

here r is the number of entries in a_1, a_2, $\ldots$, a_{k-1} that equal a_k. This quantity can also be expressed in the simpler form

$$E_{mnt} = \frac{1}{n^m}\binom{n}{2}\sum_{k>t}\binom{m}{k}(n-1)^{m-k}\left(\binom{k}{2}-\binom{t+1}{2}\right), \quad \text{for } t\ge 0.$$

Is there a simpler way yet to give the answer? Apparently not, since the generating function for given n and t is

$$\sum_m E_{mnt}z^m = \frac{n-1}{2n}\frac{z}{(1-z)^3}\left(\frac{z}{n-(n-1)z}\right)^{t+1}(z+(1-z)n(t+1)).$$

Page 583 better answer for exercise 21 — 06 Sep 2001

Replace the last several lines on page 583, beginning with 'Add the indeterminate λ ...', by the following new copy:

Add the indeterminate λ to every diagonal element of A and A^*. If $t(G)$ and $t(G^*)$ are the numbers of oriented subtrees of G and G^*, we then have $\det A = \lambda t(G) + O(\lambda^2)$, $\det A^* = \lambda t(G^*) + O(\lambda^2)$. (The number of oriented subtrees of a balanced graph is the same for any given root, by exercise 22, but we do not need that fact.)

If we group vertices V_{jk} for equal k the matrix A^* can be partitioned as shown above. Let $B_{kk'}$ be the submatrix of A^* consisting of the rows for V_{jk} and the columns for $V_{j'k'}$, for all j and j' such that V_{jk} and $V_{j'k'}$ are in G^*. By adding the 2nd, ..., mth columns of each submatrix to the first column and then subtracting the first row of each submatrix from the 2nd, ..., mth rows, the matrix A^* is transformed so that

$$B_{kk'} = \begin{pmatrix} a_{kk'} & * & \ldots & * \\ 0 & 0 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & 0 \end{pmatrix} \quad \text{for } k \neq k', \qquad B_{kk} = \begin{pmatrix} \lambda+a_{kk} & * & \ldots & * \\ 0 & \lambda+m & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & \lambda+m \end{pmatrix}.$$

The asterisks in the top rows of the transformed submatrices turn out to be irrelevant, because the determinant of A^* is now seen to be $(\lambda+m)^{(m-1)n}$ times

$$\det\begin{pmatrix} \lambda+a_{00} & a_{01} & \ldots & a_{0(n-1)} \\ a_{10} & \lambda+a_{11} & \ldots & a_{1(n-1)} \\ \vdots & \vdots & \ddots & \vdots \\ a_{(n-1)0} & a_{(n-1)1} & \ldots & \lambda+a_{(n-1)(n-1)} \end{pmatrix} = \lambda t(G) + O(\lambda^2).$$

Page 584 replacement for the top four lines — 06 Sep 2001

Notice that when $n=1$ and there are m arcs from V_0 to itself, we find in particular that exactly m^{m-1} oriented trees are possible on m nodes labeled. This result will be obtained by quite different methods in Section 2.3.4.4.

Page 613 new answer — 10 Nov 2002 MALLAT

32. Steven Crain points out that the method always frees all blocks and starts afresh before 16667 units of time have elapsed; hence the stated limit certainly exists. *Proof:* Let $u_n = n + t_n$, so that $g_n = \lfloor \frac{5}{4} \min(10000, f(u_{n-1} - n), f(u_{n-2} - n), \ldots, f(u_0 - n)) \rfloor$. Let $x_0 = 0$ and $x_1 = u_0$, and $x_{k+1} = \max(u_0, \ldots, u_{x_k - 1})$ for $k \geq 1$. If $x_k > x_{k-1}$ then

$$u_n \leq n + \frac{5}{4} f(x_k - n) = \frac{5}{4} x_k - \frac{1}{4} n \leq \frac{5}{4} x_k - \frac{1}{4} x_{k-1} \qquad \text{for } x_{k-1} \leq n < x_k;$$

therefore $x_{k+1} - x_k \leq \frac{1}{4}(x_k - x_{k-1})$, and we must have $x_k = x_{k-1}$ before reaching time $12500 + \lfloor 12500/4 \rfloor + \lfloor 12500/4^2 \rfloor + \cdots$.
